

# ENGINEERING REPORT

**Subject:** Side Weight vs. Large Balance Holes  
**Date:** 12/21/2017  
**Place:** International Training & Research Center  
**Present:** Tom Frenzel

**Purpose:**

Examine the performance characteristics of bowling balls with side weight outside of specifications compared to balls with large balance holes.

**Summary:**

Balls drilled with large balance holes tend to hook earlier than balls with large side weights.

**Data:**

Two balls from different brands were selected for this study that had large top weights and pin to center of gravity distances. First, the balls were thrown undrilled with their center of gravities shifted right of the grip center to give the ball three-ounces of side weight. Both balls were thrown on a typical house condition and then the 2017 USBC Masters pattern. The balls were thrown in alternating order with the same settings on E.A.R.L.:

|                      |                 |
|----------------------|-----------------|
| <b>Ball Speed</b>    | <b>17.2 MPH</b> |
| <b>RPM</b>           | 350 RPM         |
| <b>Axis Rotation</b> | 50 degrees      |
| <b>Axis Tilt</b>     | 10 degrees      |
| <b>Laydown</b>       | 22 board        |
| <b>Trajectory</b>    | -1.85 degrees   |

After the undrilled data with large side weights was collected, the balls were drilled with two finger holes and a thumb hole about the center of grip. They we also drilled with a large balance hole to get the balls back to legal static weights. The balance holes were also drilled to increase total differential as much as possible, but we were limited based on where the centers of gravity was located on each ball. The changes to the specifications of the bowling balls were recorded and then the balls were thrown again on the same two patterns.

# ENGINEERING REPORT

## Ball Data

When a bowling ball is drilled, the holes change the ball's mass properties. The mass properties include:

1. Total Weight (Mass)
2. Imbalance (Center of Volume to Center of Mass distance)
3. Thumb, Side, and Top Weight (imbalance components measured from the center of grip)
4. Moment of Inertia (X, Y, and Z)
5. Radius of Gyration (X, Y, and Z, RG is determined by weight and moment of inertia)

Below is a table that illustrates how the balls in this study were affected by the drilling process:

| Ball | Type          | Weight | Imbalance | Thumb  | Side  | Top    | RGx   | RGy   | RGz   | I <sub>x</sub> | I <sub>y</sub> | I <sub>z</sub> | RG Total Differential | I Total Differential |
|------|---------------|--------|-----------|--------|-------|--------|-------|-------|-------|----------------|----------------|----------------|-----------------------|----------------------|
